Parallax Compensation Attachment for the MAMIYAFLEX Model C

The PARAMENDER parallax compensator is used between the camera and the tripod head (or camera stand). The camera support of the PARAMENDER is lowered fully when focusing with the upper, focusing lens and ground-glass screen. This positions the focusing lens exactly where the picture-taking lens will be when the shutter is released for the actual exposure, so the image thrown on the focusing screen is the exact replica in reverse of the final negative impression.

After adjusting focus, use knob to elevate camera as far as it will go. Picture-taking lens is now in the position previously occupied by the focusing lens, and the negative image will match that used for focusing and composing. Parallax is completely eliminated.
